5 Subject: Design Considerations for Stream I/O

### 6 **Analysis**

7 The two unresolved issues about stream I/O, 127 and 128, suggest that there may be some  
8 serious design defects, not just some editorial fixes to be done. This paper discusses these design  
9 considerations and attempts to construct a solid foundation for resolving these two issues. It will  
10 attempt to provide a rigorous model using a general approach starting with first principles.

11 Although many of these ideas are well known and some of them are already part of the  
12 normative text of Fortran 2000, I believe that it is useful to present them in as well organized and  
13 coherent a manner as possible.

14 It is my position that stream I/O (and all other I/O access methods for that matter) are  
15 intimately connected with the host operating system and file system and must take file system  
16 properties into full consideration in order to work well.

17 The original purpose of stream I/O was to allow users of Fortran to access C-style "byte stream"  
18 files or, alternatively, files that have no internal record structure. This is explicitly stated in the  
19 two WG5 work items, 63 and 63a, proposing stream I/O.

20 Following are some design principles and assumptions that form the foundation of this analysis.

- 21 1. Implementation details should be left to the processor.
- 22 2. We should design for all commercially significant operating systems and file systems.
- 23 3. Fortran compilers should work well on a wide variety of operating systems and file systems. No  
24 one operating system or file system should dominate the design of Fortran.
- 25 4. Fortran compilers should honor the standards and conventions of the host operating system and  
26 file system(s). If the operating system and file system are silent on an issue, then the  
27 Fortran compiler is free to do as it pleases.
- 28 5. Operating systems can support more than one file system, often simultaneously on the same  
29 system. A good example is Microsoft Windows NT, which can have some disk volumes with  
30 the FAT file system and other volumes with the NTFS file system on the same system at the  
31 same time.
- 32 6. No concept of a file is universal, even though some concepts are very widespread.
- 33 7. We do not know what file systems will dominate computing 10 to 20 years from now. There is  
34 no guarantee or even a high likelihood that the file systems which are predominant today  
35 will continue to dominate computing.
- 36 8. In the next 10 to 20 years, we may have commercially significant installable file systems that  
37 are designed by parties other than the vendor of the operating system, such as commercial  
38 third parties or even by the user through development kits.
- 39 9. Stream I/O in Fortran is an access method, not some other kind of file attribute. This is a  
40 correct design decision.

1 We should rigorously distinguish the concepts of access method, record structure (a.k.a. record  
2 type), and data format. Although these three concepts are closely related, they really are  
3 independent concepts that can be clearly distinguished.

- 4 • An access method is the way that the program finds the data in a file. Previous versions of  
5 Fortran allowed only two access methods, sequential and direct. J3 is now adding stream  
6 access to Fortran 2000.
- 7 • A record structure, or record type, is the way that records are organized and marked off from  
8 one another. A file system may support more than one record structure. For example, a file  
9 system may support variable-length records, fixed-length records and stream records.
- 10 • Data format specifies whether the data is read and written using formatted input/output  
11 statements or is unformatted.

12 It may be possible to access a file of a given record structure in more than one way. This  
13 possibility is explicitly anticipated in the normative text of the Fortran 2000 draft [161:18-21,  
14 172:8-11].

15 File systems can vary widely in complexity and internal structure. At one extreme is the Unix-  
16 style concept of a file, "A file is nothing more than a stream of bytes.". At the other extreme is the  
17 OpenVMS RMS (for Record Management Services) file system, which has a very complex internal  
18 file structure and record structure. It may be useful to draw an analogy.

19 One could consider file systems to be strongly or weakly typed, just like data types in  
20 programming languages. In weakly typed languages, data objects are given a data type, but it is  
21 relatively easy to look at the data in an object as if it were of another data type without generating  
22 an error condition. In contrast, in strongly typed languages, considering a data object to be  
23 something other than the data type it was declared to be is an error and generates an error  
24 condition.

25 Similarly, file systems can be classified as weakly typed if the data in the records can be  
26 accessed as if it had two or more record structures, e.g., by variable-length records or by stream.  
27 There is little or no difference in the record structure. In contrast, in a strongly typed file system, a  
28 given record structure is carefully defined and differentiated from other record structures. If a file  
29 is created with one kind of record structure and then there is an attempt to access it as if it had a  
30 different kind of record structure, an error occurs.

31 If stream I/O is to work properly in Fortran, it must work equally well on both weakly typed  
32 and strongly typed file systems. This means that any characteristic or attribute of a file system that  
33 varies from one file system to another needs to be left to the operating system and file system.  
34 Hence, any issue which is concerned about such file system attributes is necessarily processor-  
35 dependent.

36 If a file system recognizes more than one internal structure, it may be allowable to read the data  
37 in an existing file with a given record structure only by using one particular access method or by  
38 using more than one access method. If more than one access method is allowed, the processor may  
39 be able to detect the file's record structure or the user may need to specify which record structure is  
40 in use through means not specified in the Fortran standard. An example of the latter method of  
41 detection would be to use one or more nonstandard I/O keywords which specify the internal file and  
42 record structure.

43 The same problems also exist when creating a file or writing to an existing file. Different access  
44 methods may, by default, create files with different internal file or record structures. If the host  
45 operating system or file system allows the Fortran compiler to use an access method to write to

1 more than one kind of file or record structure, then the Fortran compiler must have some way of  
2 determining which structure to use.

3 Here is an example. Consider a hypothetical file system that has at least two different record  
4 structures, variable length sequential records and stream records. It is possible for the file system  
5 to support all four of the following combinations:

<u>Access Method</u>	<u>Record Structure</u>
Sequential	Variable Length Sequential
Sequential	Stream
Stream	Variable Length Sequential
Stream	Stream

11 There is no requirement in the Fortran 2000 draft that a Fortran processor using such a file system  
12 needs to support all four combinations.

13 A related issue is how file systems mark the end of a record (EOR). There are many different  
14 ways of doing this with operating systems and file systems that are commercially important today.  
15 The following table lists the methods used by several file systems today.

<b>File System</b>	<b>EOR Method</b>
MacOS	<CR>
Microsoft Windows FAT	<CR><LF>
Microsoft Windows NTFS	<CR><LF>
Unix	<LF>
VMS RMS	Depends on record structure (record type)

## 22 **Issues**

23 Here is the full text of the two issues related to stream I/O.

24 **Issue 127:** I'm not convinced that end-of-file conditions are fully covered for formatted streams.  
25 Note that there is no endfile record in a formatted stream (and I doubt we want there to  
26 be one). A strict reading of the 2<sup>nd</sup> sentence of 9.2.3.2 would tell me that it didn't apply  
27 because the endfile wasn't a result of reading an endfile record, but that's subtle. I'd  
28 suggest explicitly adding something about sequential; didn't do that myself in case  
29 someone thinks that this should apply.

30 What happens when reading a partial record at the end of a file? We say that there may  
31 be partial records, but I don't see where we ever say what the effects of such a thing are.  
32 If there is a partial record at the end of a file, is it possible to position after it so that it is  
33 the previous record? Should, perhaps, reading past the end of a partial record be an  
34 error instead of an EOF or EOR condition? Does padding apply to partial records?  
35 Some of these questions are probably best answered elsewhere than in 9.2.3.2, but I'll  
36 lump them all into one J3 note.

37 **Issue 128:** The words in 10.5.3 about linefeeds in A output imply to me that a nonadvancing  
38 formatted stream output statement that writes a linefeed as the last character in a  
39 stream file will cause there to be an empty and incomplete record at the end of the file.  
40 Is this empty incomplete record supposed to be distinguishable from having no record?  
41 If so, I wonder how Unix-like systems are supposed to distinguish it. If not, I wonder  
42 whether we have it described correctly. Same with / editing, where this was just copied

1                   from. These holes leave me unconvinced that the description of record handling “just  
2                   works” with formatted stream I/O. This related to unresolved issue 127 about handling  
3                   of incomplete records.
