Subject: Specifications, syntax and edits for M.23: Access to status error messages
References: 97-159, 98-172 98-173r1 98-208, 98-213

1   Background

Specifications and three possible syntaxes to access status error messages were proposed in paper 98-173r1. Informal discussions suggested the "intrinsic procedure" approach is the preferred approach.

Paper 98-213, proposing the intrinsic procedure approach, was presented and discussed at meeting 147. Several issues were raised but not resolved, and the paper was withdrawn after three unsuccessful revisions. Subsequent e-mail discussion revealed that the intrinsic procedure approach does not support access to error messages produced by user-defined derived-type input/output procedures. The approach of using an ERRMSG= specifier in input/output, allocate and deallocate statements does work for this circumstance. This paper proposes specifications, syntax and edits for using an ERRMSG= specifier in input/output, allocate and deallocate statements to provide access to status messages.

2   Specifications and Syntax

Define an ERRMSG=*errmsg-variable* specifier for use in input/output, allocate and deallocate statements. The *errmsg-variable* shall be a default character scalar. The `errmsg` argument of the derived-type input/output procedures shall have the same characteristics as the *errmsg-variable*.

3   Edits

Edits refer to 99-007. Page and line numbers are displayed in the margin. Absent other instructions, a page and line number or line number range implies all of the indicated text is to be replaced by immediately following text, while a page and line number followed by + indicates that immediately following text is to be inserted after the indicated line. Remarks for the editor are noted in the margin, or appear between [and] in the text.

9.9 Error processing

Error processing takes place if an error occurs during execution of input/output statements that have IOSTAT= or ERR= specifiers, an end-of-file condition occurs during execution of READ or WAIT statements that have IOSTAT= or END= specifiers, or an end-of-record condition occurs during execution of WAIT or nonadvancing read statements that have EOR= specifiers.

[Editor: Move 9.5.1.5 here, change its title to **9.9.1 IOSTAT= specifier**.]

9.9.2 ERRMSG= specifier

If an error, end-of-file or end-of-record condition occurs during execution of an input/output statement the processor shall assign a message explaining the condition to the *errmsg-variable*.

If no error condition, end-of-file condition, or end-of-record condition occurs during execution of an input/output statement, the processor shall not change the value of the *errmsg-variable*.

[Editor: Move 9.5.1.6 − 9.5.1.8 here, changing their numbers to 9.9.3 − 5, and their titles to "ERR= specifier", "END= specifier" and "EOR= specifier" respectively.]

A variable that may become defined or undefined as a result of its use in a specifier in an input/output statement, or any associated entity, shall not appear in another specifier in the same statement, nor shall it appear in or be associated with any entity in a data transfer list, *namelist-group-object-list*, or *do-variable* of an *io-implied-do*, in the same data transfer statement. If it is an array element reference, its subscript values shall not be affected by the data transfer, the *io-implied-do* processing, or the definition or evaluation of any other specifier in the *io-control-spec-list*, in the same statement.	207:34+ *Overkill?*
